"Writing code a computer can understand is science. Writing code other programmers can understand is an art."

— **Jason Gorman**

"I am rarely happier than when spending an entire day programming my computer to perform automatically a task that would otherwise take me a good ten seconds to do by hand."

— **Douglas Adams**

Problem 1 An n digit integer $(a_1 a_2 \ldots a_n)$, where each digit $a_i \in \{0, 1, \ldots, 9\}$, is said to have *unique digits* if no digits are repeated, i.e., there is no i, j such that $a_i = a_j$ $(i \neq j)$.

Verify whether an inputted number has *unique digits*.

Solution The problem involves simply counting the number of occurences of each digit in the given number and checking whether any of them exceed 1.

Source Code

```java
public class Unique {
    public static void main (String[] args) {
        try {
            long number = Long.parseLong(args[0]);
            if (isUnique(number)) {
                System.out.println("Unique Number!");
            } else {
                System.out.println("Not a Unique Number!");
            }
        } catch (NumberFormatException | IndexOutOfBoundsException e) {
            System.out.println("Enter 1 argument (number[integer])!");
        }
    }

    public static boolean isUnique (long number) {
        int[] count = new int[10];
        for (long n = Math.abs(number); n > 0; n /= 10) {
            int digit = (int) n % 10;
            count[digit]++;
            if (count[digit] > 1){
                return false;
            }
        }
        return true;
    }
}
```

Problem 2 A *partition* of a positive integer n is defined as a collection of other positive integers such that their sum is equal to n. Thus, if $(a_1, a_2, \ldots, a_k)$ is a partition of n,

$$n \;=\; a_1 + a_2 + \cdots + a_k \qquad\qquad (a_i \in \mathbb{Z}^+)$$

Display every *unique partition* of an inputted number.

Solution   This problem can be solved elegantly using *recursion*[1].

Source Code

```
1
2  public class Partition {
3      public static void main (String[] args) {
4          try {
5              int target = Integer.parseInt(args[0]);
6              if (target < 1) {
7                  throw new NumberFormatException();
8              }
9              partition(target);
10         } catch (NumberFormatException | IndexOutOfBoundsException e) {
11             System.out.println("Enter 1 argument (number[natural
                   number])!");
12         }
13     }
14     public static void partition (int target) {
15         partition(target, target, "");
16     }
17     public static void partition (int target, int previousTerm, String suffix) {
18         if (target == 0)
19             System.out.println(suffix);
20         for (int i = 1; i <= target && i <= previousTerm; i++)
21             partition(target - i, i, suffix + " " + i);
22     }
23 }
```

---

[1]Recursion occurs when a thing is defined in terms of itself or of its type.

Problem 3   A *Caesar cipher* is a type of monoalphabetic substitution cipher in which each letter in the plaintext is replaced by a letter some fixed number of positions down the alphabet. The positions are circular, i.e., after reaching Z, the position wraps around to A. For example, following is some encrypted text, using a right shift of 5.

```
Plain:   ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher:  FGHIJKLMNOPQRSTUVWXYZABCDE
```

Thus, after mapping the alphabet according to the scheme $A \mapsto 0, B \mapsto 1, \ldots, Z \mapsto 23$, we can define an encryption function E_n, in which a letter x is shifted rightwards by n as follows.

$$E_n(x) \;=\; (x + n) \mod 26$$

The corresponding decryption function D_n is simply

$$D_n(x) \;=\; (x - n) \mod 26$$

Implement a simple version of a *Caesar cipher*, encrypting capitalized plaintext by shifting it by a given value. Interpret positive shifts as rightwards, negative as leftwards.

Solution

Source Code

```java
1  public class CaesarShift {
2      public static void main (String[] args) {
3          try {
4              int shift = Integer.parseInt(args[0]) % 26;
5              String plaintext = args[1].toUpperCase();
6              String ciphertext = "";
7              for (int i = 0; i < plaintext.length(); i++) {
8                  char plain = plaintext.charAt(i);
9                  char crypt = ' ';
10                 if ('A' <= plain && plain <= 'Z') {
11                     crypt = numToChar(charToNum(plain) + shift);
12                 } else {
13                     crypt = plain;
14                 }
15                 ciphertext += crypt;
```

```java
16                      }
17                      System.out.println(ciphertext);
18              } catch (NumberFormatException | IndexOutOfBoundsException e) {
19                      System.out.println("Enter 2 arguments (shift[integer],
                            plaintext[text])!");
20              }
21      }
22
23      public static int charToNum (char letter) {
24              return Character.toUpperCase(letter) - 'A';
25      }
26
27      public static char numToChar (int number) {
28              return (char) ('A' + Math.floorMod(number, 26));
29      }
30  }
```

> *naming things, and off-by-1 errors."*

> — **Leon Bambrick**

Problem 4 A *palindrome* is a sequence of characters which reads the same backwards as well as forwards. For example, `madam`, `racecar` and `kayak` are words which are palindromes. Similarly, the sentence "`A man, a plan, a canal -- Panama!`" is also a plaindrome.

Analyze a sentence of input and display all *words* which are palindromes. If the entire *sentence* is also a palindrome, display it as well.

(A word is an unbroken sequence of characters, separated from other words by whitespace. Ignore single letter words such as I *and* a*. Ignore punctuation, numeric digits, whitespace and case while analyzing the entire sentence.)*

Solution

Source Code

```java
import java.util.Scanner;

public class Palindrome {
    public static void main (String[] args) {
        System.out.print("Enter your sentence : ");
        String sentence = (new Scanner(System.in)).nextLine().trim();
        boolean foundPalindrome = false;
        System.out.println("Palindromes : ");
        foundPalindrome |= checkWords(sentence);
        foundPalindrome |= checkSentence(sentence);
        if (!foundPalindrome) {
            System.out.println("(No palindromes found!)");
        }
    }

    public static boolean checkWords (String sentence) {
        boolean foundPalindrome = false;
        int start = -1;
        int end = 0;
        while (end < sentence.length()) {
            while (Character.isWhitespace(sentence.charAt(++start)));
            end = start;
```

```java
23                        while (end < sentence.length() &&
                              !Character.isWhitespace(sentence.charAt(end++)));
24                    String word = sentence.substring(start, end).trim();
25                    if (isPalindrome(word)) {
26                          foundPalindrome = true;
27                          System.out.println(getAlphabets(word));
28                    }
29                    start = end - 1;
30              }
31              return foundPalindrome;
32        }

33

34        public static boolean checkSentence (String sentence) {
35              if (isPalindrome(sentence)) {
36                    System.out.println("The sentence '" + sentence + "' is a
                          palindrome.");
37                    return true;
38              }
39              return false;
40        }

41

42        public static boolean isPalindrome (String text) {
43              String rawText = getAlphabets(text).toUpperCase();
44              for (int i = 0, j = rawText.length() - 1; i < j; i++, j--) {
45                    if (rawText.charAt(i) != rawText.charAt(j)) {
46                          return false;
47                    }
48              }
49              return (rawText.length() > 1);
50        }

51

52        public static String getAlphabets (String text) {
53              String rawText = "";
54              for (int i = 0; i < text.length(); i++) {
55                    if (Character.isAlphabetic(text.charAt(i))) {
56                          rawText += text.charAt(i);
57                    }
58              }
59              return rawText;
60        }
61 }
```

> — **Paul Graham**

Problem 5   A *prime number* (or a *prime*) is a natural number greater than 1 that has no positive divisors other than 1 and itself.

Display all primes upto a given limit, along with their number.

Solution   This problem could be tackled in a number of ways. We could define a function for checking the primality of a given number, then iterate through all numbers in the required range. A common way of checking for primality is *trial division*. It consists of testing whether the number n is a multiple of any integer between 2 and $\sqrt{n}$. Although this works well enough for small numbers, repeating this consecutively for very large inputs is tedious and inefficient. Since the problem consists of identifying primes in a *range*, and not individually, we can make use of more efficient methods.

The *Sieve of Eratosthenes* is a simple, ancient algorithm for finding all prime numbers up to any given limit. It does so by iteratively marking as composite the multiples of each prime, starting with the first prime number, 2. As a result, when a prime p is found, none of its multiples will be tested further for primality — they are eliminated early on. In comparison, *trial division* has worse theoretical complexity than that of the *Sieve of Eratosthenes* in generating ranges of primes. When testing each prime, the optimal trial division algorithm uses all prime numbers not exceeding its square root, whereas the Sieve of Eratosthenes produces each composite from its prime factors only.

Source Code

```
1  public class SieveOfEratosthenes {
2        private final int upperLimit;
3        private boolean[] primes;
4
5        public SieveOfEratosthenes (int upperLimit) {
6              this.upperLimit = upperLimit;
7              this.initPrimes();
8        }
9
10       public boolean[] getPrimes () {
11             return primes;
12       }
13
14       public void initPrimes () {
```

```
15              this.primes = new boolean[upperLimit];
16              primes[0] = false;
17              primes[1] = false;
18              for (int i = 2; i < upperLimit; i++)
19                  primes[i] = true;
20          }
21
22      public void sievePrimes () {
23              int prime = 2;
24              while ((prime * prime) < upperLimit) {
25                  int multiple = prime * prime;
26                  while (multiple < upperLimit) {
27                      primes[multiple] = false;
28                      multiple += prime;
29                  }
30                  while (!primes[++prime]);
31              }
32          }
33  }
```

3               try {
4                   int upperLimit = Integer.parseInt(args[0]);
5                   if (upperLimit < 2) {
6                       throw new NumberFormatException();
7                   }
8                   SieveOfEratosthenes sieve = new
                        SieveOfEratosthenes(upperLimit);
9                   sieve.sievePrimes();
10                  showPrimes(sieve.getPrimes());
11              } catch (NumberFormatException | IndexOutOfBoundsException e) {
12                  System.out.println("Enter 1 argument (limit[integer, >1])!");
13                  System.out.println("(Primes will be dislayed up to, not
                        including 'limit')");
14              }
15          }
16
17      public static void showPrimes (boolean[] primes) {
18              int primeCount = 0;
19              int maxLength = Integer.toString(primes.length).length();
20              for (int i = 0; i < primes.length; i++) {
21                  if (primes[i]) {
22                      System.out.printf("%" + maxLength + "d ", i);
23                      primeCount++;
```

```
24                        }
25                }
26                System.out.println("\nTotal number of primes : " + primeCount);
27        }
28  }
```

Problem 6 Design a simple interface for an examiner which can format and display marks scored by a group of students in a particular examination. Calculate the percentage scored by each candidate and display the list of students and percentages in an ASCII bar chart, arranged alphabetically.

Solution

Source Code

```java
public class Marksheet {
        public static final int SCREEN_WIDTH = 100;
        private final double maxMarks;
        private final int numberOfStudents;
        private int lastStudent;
        private String[] names;
        private double[] marks;

        public Marksheet (double maxMarks, int numberOfStudents) {
                this.maxMarks = maxMarks;
                this.numberOfStudents = numberOfStudents;
                this.names = new String[numberOfStudents];
                this.marks = new double[numberOfStudents];
                this.lastStudent = -1;
        }

        public boolean addMarks (String name, double score) {
                try {
                        names[++lastStudent] = name;
                        marks[lastStudent] = score;
                        return true;
                } catch (IndexOutOfBoundsException e) {
                        return false;
                }
        }

        public void displayChart () {
                System.out.println(Marksheet.multiplyString("-",
                    Marksheet.SCREEN_WIDTH));
                for (int i = 0; i <= lastStudent; i++) {
                        double fraction = marks[i] / maxMarks;
```

```java
                        String name = (names[i].length() < 16)
                                    ? names[i]
                                    : (names[i].substring(0,13) + "...");
                    int points = (int) (fraction * (SCREEN_WIDTH - 34));
                    String bar = multiplyString("*", points)
                            + multiplyString(" ", SCREEN_WIDTH - 34 - points);
                    System.out.printf("| %16s | %s | %6.2f %% |%n"

Problem 7 The *determinant* of a square matrix $A_{n,n}$ is defined recursively as follows.

$$det(A_{n,n}) = \begin{vmatrix} a_{1,1} & a_{1,2} & \cdots & a_{1,n} \\ a_{2,1} & a_{2,2} & \cdots & a_{2,n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & a_{n,2} & \cdots & a_{n,n} \end{vmatrix} = \sum_{j=1}^{n}(-1)^{i+j}a_{i,j} \cdot det(M_{i,j})$$

where $M_{i,j}$ is defined as the minor of $A_{n,n}$, an $(n-1) \times (n-1)$ matrix formed by removing the ith row and jth column from $A_{n,n}$.

The determinant of a (2×2) matrix is simply given by

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

For example, the determinant of a (3×3) matrix is given by the following expression.

$$\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix} = a\begin{vmatrix} e & f \\ h & i \end{vmatrix} - b\begin{vmatrix} d & f \\ g & i \end{vmatrix} + c\begin{vmatrix} d & e \\ g & h \end{vmatrix}$$

$$= aei + bfg + cdh - ceg - bdi - afh$$

Calculate the *determinant* of an inputted $(n \times n)$ square matrix.

Solution

Source Code

```
public class Matrix {

— **Scott W. Ambler**

Problem 8   A *Knight's Tour* is a sequence of moves of a knight on a chessboard such that the *knight* visits every square only once. If the knight ends on a square that is one knight's move from the beginning square, the tour is *closed* forming a closed loop, otherwise it is *open.*

There are many ways of constructing such paths on an empty board. On an 8×8 board, there are no less than $26,534,728,821,064$ *directed*[2] *closed* tours. Below is one of them.

Construct a *Knight's Tour* (*open* or *closed*) on an $n \times n$ board, starting from a given square.

(Mark each square with the move number on which the knight landed on it. Mark the starting square 1.)

---

[2]Two tours along the same path that travel in opposite directions are counted separately, as are rotations and reflections.

18

Solution   A knight on a chessboard can move to a square that is two squares away horizontally and one square vertically, or two squares vertically and one square horizontally.
The mobility of a knight can make varies greatly with its position on the board — near the centre, it can jump to one of 8 squares while when in a corner, it can jump to only 2. On the other hand, the number of possible *sequences* of squares a knight can traverse grows extremely quickly. Although it may seem that a simple *brute force* search can quickly find one of *trillions* of solutions, there are approximately 4×10^{51} different paths to consider on an 8×8 board. For even larger boards, iterating through every possible path is clearly impractical.[citation needed]

This problem calls for implementing a *backtracking*[3] *algorithm*, coupled with some *heuristic*[4] to speed up the search. One such heuristic is *Warnsdorf's Rule*.

> The knight is moved so that it always proceeds to the square from which the knight will have the *fewest* onward moves.

This allows us to define a ranking alorithm for each possible path — the positions which result in the smallest number of further moves, or is furthest away from the board's centre will be investigated first. In case of a tie, we can either proceed without making any changes to the already existing positions, or introduce a random element. This has the effect of producing different results on successive executions, giving a variety of solutions.

One drawback of resolving ties randomly is that an early "wrong" choice in the position tree can force the calculation of every resulting path without reaching a solution, effectively reducing the algorithm to a brute force search. This is especially problematic

---

[3]Backtracking is a general algorithm for finding some or all solutions to some computational problems that incrementally builds candidates to the solutions, and abandons each partial candidate ("backtracks") as soon as it determines that the candidate cannot possibly be completed to a valid solution.

[4]A heuristic technique is any approach to problem solving that employs a practical method not guaranteed to be optimal or perfect, but sufficient for the immediate goals. Where finding an optimal solution is impossible or impractical, heuristic methods can be used to speed up the process of finding a satisfactory solution.

for large boards, where it may take hours to backtrack and reach a solution. Thus, the "randomness factor" should be adjusted according to the board size.

A high randomness can be useful for searching specifically for *closed tours*, as a randomness of 0 simply produces the same solution every time (which may or may not be closed). Below are some tours generated by the program.
The tendency of the path to remain close to the edges of the board is clearly evident.
